## ABSTRACT

In this Miscellaneous Bulletin a research project funded by the Fishing Industry Research Committee is reported. The aim of this project was to derive price spreads for the major fish species marketed in Sydney. Weekly auction-retail price spreads for fifteen categories of fish and two categories of crustacea, over the period October 1982 to June 1986, are calculated and reported. The data are explained, a detailed account of the calculation procedures is given, the resultant price spreads are presented in both tabular and graphical forms, and trends in the spreads, hypothesised factors determining their magnitude and variability, and inter-relationships between the spreads, are discussed. Further quantitative research employing these spreads is proposed.

## ACKNOWLEDGEMENTS

This paper forms the final report to the Fishing Industry Research Committee for the project "Analysis of Fish Pricing in New South Wales: Relationships Between Prices at Auction and Retail". The support of the Committee in assisting with this research is gratefully acknowledged.

The report would not have been possible without the support and assistance of a considerable number of co-operators. The authors wish to thank the NSW Fish Marketing Authority who graciously provided us with the auction price data, and the Authority personnel, particularly Gus Dannoun, Robert Steele and Annette Forest, and the members of the Master Fish Merchants' Association who enlightened us on both NSW and interstate fish marketing operations.

Our thanks are also extended to Dr David Godden for advice and support on many aspects of this project, especially assistance with computer programming.

Our gratitude is also extended to typists Sandra Cullen, Shane de Wet and Cindy Bussell who were always willing to do more than expected on a difficult manuscript. Their work is always appreciated.

## 1. INTRODUCTION

The retail value of fish production includes both payments to fishermen and the value added in marketing the fish. The value to fishermen of finfish production from New South Wales (NSW) fisheries was over \$26 million in 1984/85. The value added in marketing, if a conservative markup of 40% is assumed, would have been some \$10.4 million.

There is clearly strong economic interdependence between the production and marketing sectors of the fishing industry. The costs of marketing fish have relevance for returns to fishermen as well as for prices to consumers.

Despite the undoubted significance of the fish marketing sector for the viability of the wider fish products industry, research in this industry has been almost focussed solely on the catching sector. This paper contributes to a greater understanding of the fish marketing sector by providing information by species on the extent of the price spread between auction and retail at the Sydney Fish Markets, on the trends in these spreads over time, and on the possible factors which determine why these spreads vary over species and over time.

In this paper, weekly auction-retail price spreads for fifteen categories of fish and two categories of crustacea marketed in the Sydney area between October 1982 and June 1986, are calculated and reported. The price spreads are calculated by the comparative price method, where for each category the spreads are measured as the difference between the auction price at the Sydney Fish Markets and an average retail price in the Sydney area, for a comparable retail weight. The fifteen fish categories are gemfish, redfish, flathead, morwong, mullet, trevally, snapper, whiting, bream, kingfish, ling, John dory, Mirror dory, mulloway and garfish. King prawns and school prawns constitute the crustacea categories.

The fish marketing system in NSW is briefly described in the second section of this paper. The concept of price spreads, methods of calculation and uses of price spreads are discussed in the third section. An explanation of the data and a detailed account of the procedures used to calculate the weekly price spreads for fish are contained in Section Four. The price spreads are presented in Section Five, which also contains a discussion of trends. Factors determining the magnitude and variability in, and inter-relationships between, these price spreads are also hypothesized in this section. Conclusions are presented in Section 6.

## 2. FISH MARKETING IN NEW SOUTH WALES

### 2.1 Marketing Regulations in New South Wales

The fishing industry in NSW is regulated under the NSW Fisheries and Oyster Farms Act of 1935 which is administered by the Department of Agriculture. All commercial fishermen and vessels fishing in NSW waters must be licensed. Under present fisheries management regimes, the number of boats in NSW fisheries is restricted.

Marketing regulation requires that all fish caught and intended for sale in NSW must be consigned to a registered market. Interstate marketing of fish is free of this requirement under the provisions of Section 92 of the Australian Constitution. The Sydney Fish Market and 23 co-operative trading societies are registered markets. Fishermen receive the value of their fish determined at the point of sale less a flat commission rate (approximately 3% for consignments to co-operatives). Co-operative trading societies have the option of either disposing of fish locally, interstate, or overseas, or consigning it to the Sydney Fish Market. A co-operative must be separately licensed for export.

### 2.2 The New South Wales Fish Marketing Authority

In 1963, the Fisheries and Oyster Farms Act was amended to provide for the establishment of the NSW Fish Marketing Authority (FMA). The Authority is a financially independent statutory body whose primary functions are to promote orderly and efficient marketing of fish in NSW through a system of marketing licenses and to administer the Sydney Fish Market. Regulation dictates that all fish caught in NSW and intended for sale in the County of Cumberland (Sydney) must be consigned to the FMA for sale.

The specific aim of orderly marketing of fish is to minimise price fluctuations resulting from gluts and shortages of supply inherent in the fishing industry. In addition, the regulated market system provides the opportunity to enforce minimum size and catch regulations enacted to protect the fisheries from biological exploitation and to ensure that fish unfit for human consumption is not marketed.

The operations of the FMA are funded by revenue derived from the commission fees of those consigning fish to the Sydney Markets or directly to Sydney processors and from rent for retail shops and cleaning facilities contained within the Sydney Fish Market complex at Blackwattle Bay. Fish forwarded for auction by co-operative trading societies incur a 9% commission rate. Fishermen consigning fish directly to market are charged a commission of 12%, or 9% if annual supplies exceed \$200,000 in value. Market development and promotion work is undertaken by the FMA and surplus funds are made available as long-term low-interest loans to co-operative trading societies for improving or expanding their facilities.

### 2.3 Sydney Fish Market Auctions

The FMA conducts auctions of fish at its premises five days a week. Fish is delivered overnight and auctioning begins at 5.20 am. The auction is generally completed by mid morning allowing fresh fish to be in the shops for that day's trading.

It is estimated that approximately 65% of the NSW catch of fish and crustacea are auctioned at the Sydney Fish Market. Fish is sold whole by public auction in ten crate lots (a crate is either 10, 25 or 32 kg) with the highest bidder having the option on the number of crates he chooses to purchase, and any remaining crates in the lot offered at a decreasing price clockwise around the auction floor. There are over 400 buyers registered at the markets with an estimated 200 buyers purchasing fish on any one day. The majority of buyers are retail fish merchants in the Sydney area. It is estimated that 3,000 crates are auctioned on an average day's trading although the throughput on any one day may range from several hundred to 6,000 crates.

### 2.4 Sydney Retail Marketing

The majority of fresh fish retailed in the Sydney area is sold in specialist fish shops. The exact number of fish shops in the Sydney area is not known, although at least one shop appears to be located in most suburbs. These outlets range from large complexes stocking a wide variety of fish and crustaceans to smaller "fish and chip" shops offering a limited range of cooked and uncooked fish. Fresh fish supplies are supplemented by frozen fish imported from interstate and overseas, although these tend to be limited to a few species such as gemfish, flounder, sole and some dory.

Although fish is sold unprocessed on the auction floor, the majority of fish is retailed as fillets, cutlets or gutted whole. Processing is the responsibility of the retailer and is undertaken either by himself, or by a salaried or contract processor.

### 3. THE CONCEPT OF PRICE SPREADS

#### 3.1 Price Spreads Defined

The price spread or (marketing margin) is defined as the difference between the price of a commodity at one level of the market and the price of an equivalent quantity at another level of the market (Hodan 1972; Griffith and Whitelaw 1974; Tomek and Robinson 1981). This could be the difference between the auction and wholesale prices (the wholesale spread), or the wholesale and retail price (the retail spread). Alternatively, marketing margins may be defined as the physical and money costs of marketing plus profit margins (Thomsen 1951). Physical costs are the value of product shrinkage that occurs between two market levels including liveweight loss, slaughtering loss, processing loss and weight loss due to post catch tissue degradation and dehydration. Money costs are costs incurred through financial transactions in providing processing, distribution, storage, packaging and other marketing services.

The fresh domestic fish marketing system is relatively simple with the retailer as the only distinct market intermediary. Co-operative trading societies and the FMA provide services including transport, storage and an auction system on a contract basis. They do not take possession of the product. Processing loss is the major physical cost component of the marketing margin. Monetary cost components include transport, processing labour and shop overhead costs.

Price spreads have received the attention of both researchers and consumer groups. As absolute figures, price spreads may only be interpreted as an indication of the gross value of the marketing sector. Correctly calculated, they can be utilized to examine market structure and efficiency, to identify resource misallocation and to determine the effect on factor and product markets of changes in price formation policies.

Changes in price spreads have become an important issue in the primary product sector. Increases (or decreases) in the costs of marketing services are borne by the sector facing the more inelastic supply and demand conditions. Fisher (1981) has suggested that the primary producer is disadvantaged by increases in the costs of marketing due to inflexibility in production (in the short term) and the inability to influence final product demand.

It should be noted that price spreads alone are not an indication of the profitability or efficiency of market intermediaries. Comparisons of price spreads generally cannot be made across industries due to differences in product and input costs, services performed and industry structure.

#### 3.2 Methods of Calculating Price Spreads

##### 3.2.1 Sectoral Approach (National Accounts)

This method of calculating price spreads utilizes national accounts data to estimate the size of the food processing and distribution sector of the economy. The OECD (1981, p.19) has outlined the following approach to estimate national consumer expenditure on processing and distribution.

$$C_{PD} = C_E - VP_D - VP_I$$

where:

$C_{PD}$  = Consumer expenditure on processing and distribution

$C_E$  = Consumer expenditure on food

$VP_D$  = Value of domestic food production

$VP_I$  = Value of imported food

A national expenditure approach to calculating price spreads, while providing a general estimate of the total value of the aggregate marketing sector, does not generally allow a detailed investigation of price spreads for individual foods. National production and expenditure data are generally aggregated both over time and commodities. Inter-relationships between products in the same commodity group cannot be identified using aggregated data.

### 3.2.2 Functional Approach (Trading Accounts)

The functional approach uses financial records of individual firms involved in adding services to food products to calculate price spreads. Gross margins are calculated by subtracting the cost of the commodities to the firm from the total value of sales.

A common difficulty in utilizing the functional approach is the link between marketing decisions and operational costs in multi-product firms. As both the auction and retail sectors are trading solely in fish, this would not be an issue in the fish marketing industry. The difficulty in using this approach lies in identifying a firm which is representative of the entire sector. As previously discussed, fish retail shops vary widely.

### 3.2.3 Product Approach (Comparative Price Method)

The product approach compares the price of an equivalent quantity of a commodity at two separate marketing levels, with the difference known as the price spread or margin for marketing inputs. The comparative price method of calculating commodity price spreads is widely used and accepted, especially for meats (Griffith and Whitelaw, 1975; Duewer, 1969), and its use, therefore, allows comparison with other studies. It has advantages over both of the previous approaches in terms of disaggregation, separability and sector-wide relevance. Observation of individual products within commodity groups is possible. Most importantly the data available facilitates this method.

The comparative price approach is the simple difference between prices of a commodity at different market levels where the commodity is of homogeneous quality and is not transformed between markets. For most primary product commodities, however, primary product quality varies widely. Many commodities undergo extensive product transformation between markets and are stored for a time. The varying prices of different species and size grades within species indicate that fish is not a homogeneous product.

Product transformation occurs between auction and retail with large losses in product due to gutting and filleting. A simple comparison of retail and auction prices is therefore not sufficient to accurately calculate auction-retail price spreads of most primary products, including fish.

Price data must be collected for a representative and consistent quality of commodity at all market levels. If product transformation occurs, conversion factors are required at each market level to express the commodity in comparable terms. The convention is to convert the commodity to retail weight equivalent. It is here that adjustments for product loss due to preparation for retail sale are also taken into account. The storing of a commodity also requires adjustments to account for the cost of the storage.

### 3.3 Previous Research

The NSW Department of Agriculture regularly calculates price spreads for red meats by the comparative price method. Irish (1972) and then Griffith and Whitelaw (1975) established the initial methodology used to calculate these price spreads. These calculation procedures were updated in 1980 to account for changes in carcass composition, cutting practices, shrinkage, livestock type and by-product allowances (Griffith et.al. 1980).

Griffith and Whitelaw (1975) based their methodology upon the general principles of the comparative price method outlined by Duewer (1969). With regard to data, collection of all prices (retail, wholesale, and auction) should be geographically representative, consistent and cover all product forms. Retail prices should be weighted according to volume sold at normal and "special" prices. Both wholesale and auction prices should be adjusted to retail weight equivalents to account for physical losses and by-products.

## 4. METHODOLOGY

### 4.1 Approach Selected

The comparative price procedures have been employed to calculate auction-retail price spreads for fish in NSW, primarily because it was the most appropriate method to achieve the aims of the study and the data were available. Auction prices are adjusted to retail weight equivalents and they are net of all retail marketing costs. It was assumed retail prices were implicitly weighted by normal and "special" prices on collection due to the inability of the fish retail sector to store inventory. The Sydney Fish Market auctions handle all of the fresh fish legally entering the Sydney area. Prices of all grades of each fish category have been collected. It is assumed retail prices are representative of Sydney. All significant retail processed forms of each fish category are represented.

### 4.2 Data

Fifteen individual categories of finfish and two categories of prawns were chosen as representative of the Sydney retail market for fresh seafood. These finfish categories represent the majority of the fresh fish market in NSW, accounting for over 70% of both the NSW catch and the Sydney Fish Market throughput during the period examined (Table 1). As the supply and demand conditions for finfish are diverse, fish from each of the three major NSW fisheries and with several seasonal patterns were chosen. The fish species aggregated in each category as well as their fisheries and seasonality are presented in Table 2. Cooked King and school prawns are traditionally major retail seafood products in Australia.

Price spreads are calculated on a weekly basis. Further aggregation of the price data would mask the price fluctuations due to short term gluts and shortages of supply. Although daily data would better illustrate the price movements of the fishing industry where the market clears daily, retail price data are not available on a daily basis.

Auction price data were collected from the NSW FMA which records daily fish auction prices by species and size grades. The weekly auction price is a weighted average (by quantity sold) of individual purchases throughout the week.

Retail price data of individual fish categories in various processed forms are collected by the Department of Agriculture through a weekly survey of fish retail outlets in the Sydney area. It is assumed that the retail prices of these outlets are representative of Sydney retail prices. The weekly price reported is a simple unweighted average of collected prices.

Table 1 : Percentage of NSW Finfish Catch and Sydney Fish Market Throughput, 1982-83 and 1983-84<sup>1</sup>

Species	1982-83		1983-84	
	% of NSW catch	% of SFM throughput	% of NSW <sup>2</sup> catch	% of SFM throughput
Gemfish	12.18	17.07	11.38	16.12

2. Preliminary figures.

#### 4.3 Calculation Procedures

The auction-retail price spread for individual fish categories is expressed as the difference between the retail price and an adjusted auction price.

The following definitions have been used to calculate the retail price spreads.

##### 4.3.1 Retail Price

The per kilogram price at the retail level including pricing specials. Where prices are collected for more than one processed form of a fish category, a composite price was calculated from a weighted average of retail prices for each processed form. Weights are based on average retail

Table 2 : Retail Fish Species and Supply Conditions

proportions sold in each processed form (Table 3). For example, the weekly price of mullet is calculated as 0.5 of the weekly retail price of fillets plus 0.5 of the weekly retail price of whole mullet.

#### 4.3.2 Auction Price

A composite price for each fish category was derived from a weighted average of individual species or size grades as recorded at the auction level. The "total" fish classification was calculated as the sum of processed forms of that classification to allow for species and size grades specific to processed forms (Table 4). As another example, small grade

snapper are sold as whole fish but not as fillets or cutlets, whereas large grade snapper are processed to all three forms. Weekly auction throughput of species and size grades were used as the weights. The total fish classification was also weighted according to average retail proportions sold in each processed form.

The auction price was further weighted by the average recovery rate from processing to express the adjusted auction price in retail weight equivalents. Recovery rates are specific to fish categories and processing (Table 5).

## 5. RESULTS

### 5.1 Data Figures

Graphical representations of the price spreads of fish and crustacea marketed in the Sydney area between October 1982 and June 1986 are presented in figures 5.1 to 5.17. Tables reporting the data are contained in the Appendix. Also contained in the Appendix are price spreads calculated for the processed forms of the various fish categories.

It should be noted that in the tables there are dates where price spreads are not calculated. This is usually caused by missing retail price data, or less commonly, by missing auction price data. Where this discontinuity of data impaired the presentation of the graphs, a simple average retail price was calculated using the preceding and following weeks data, provided that the discontinuity did not exceed three weeks. If so, a gap is evident in the graphs.

### 5.2 Interpretations of the Data

In this Section, trends within the weekly prices and price spreads for the individual species and relationships between the species, are discussed and evaluated. There is considerable week-to-week variation in all species however, so the overall trends are not as clear as would be the case for many other food products.

#### 5.2.1 Movements Over Time and Across Species

##### (a) Price levelling

In most species, a characteristic of the data is that the retail price is more stable than the adjusted auction price. This pattern of behaviour by retailers is similar to that found in meat retailing (Griffith 1974), and is known as price levelling. Retailers maintain a relatively constant price to consumers in the face of fluctuating auction prices, so that the auction-retail spread varies inversely to the auction price. Price levelling is typically a short term phenomenon however, and over time retail prices tend to change in line with changes in auction prices. The reasons for this behaviour and for price averaging is explained in Parish (1967).

Thus in the figures and in the tables in the Appendix, it is apparent that the auction-retail price spread is more variable than the retail price and tends to move in the opposite direction to the auction price. An extreme case of this type of price levelling behaviour occurs in some species just before the Christmas and Easter holiday periods when the calculated price spread is very low or negative. Examples of species in comparatively high demand include gemfish, snapper, the Dorys, whiting and both prawn species. In these cases, the retailers are hoping to attract customers into their store at peak demand periods by offering low prices relative to costs, but then to recoup those relatively small margins in subsequent weeks.

##### (b) Price averaging

Another pricing practice employed by fish retailers evident in the data is price averaging, where retailers set a relatively high spread on some species

to compensate for low spreads on other species.

Thus, the negative spreads evident for some species near Christmas, for example, are offset by relatively large spreads for other species at that time. More generally, some medium and lower priced fish species such as redfish, flathead, trevally, morwong, mullet, ling, garfish and kingfish show very few, if any, instances of negative price spreads. However, there are a substantial number of instances of negative or very small auction-retail price spreads for species such as snapper, whiting, John dory and mullet. The costs of the marketing services embodied in the retailing of the latter group of fish are subsidised by higher price spreads achieved from the first group of fish. Even within this first group, spreads for some fish such as ling are approximately double those for other fish such as mullet and trevally.

A similar pattern occurs between the prawn species, where the price spread for King prawns appears to be used to subsidise the spread on School prawn, which exhibits a substantial number of instances of very low or negative spreads.

### 5.2.2 Effects of Supply Conditions

As reported in Table 2 and evident in the data tables and figures, some species have distinct seasonal supply conditions. There are very few instances where seasonality in supply prevents any supplies at all of those species being auctioned at the Sydney Fish Market, because of the wide range in latitude of NSW fisheries and the movement of supplies from interstate. It is apparent though that during the periods of greatest supplies, prices are depressed relative to the rest of the year. Thus, prices of gemfish, ling and Mirror dory are lower in winter than in other seasons, the price of redfish is lower in spring, and the prices of flathead, mullet and bream tend to be lower during the autumn.

For one species in particular, Mirror dory, it is evident that seasonality in supply has a substantial effect on availability at retail if not at auction. During the summer and autumn, the off-season for Mirror dory, there are many weeks (especially during late 1983 to early 1984) when no retail price quotes could be obtained.

### 5.2.3 Effects of Demand Conditions

The Easter and Christmas holiday periods are high demand periods for fish. The retail prices of most species tend to be higher during these periods, although there are instances of short run price levelling over these times of the year.

For some of the higher priced fish such as whiting and John dory, there is very little being sold in retail shops and there are many instances of no retail availability. For example, John dory was virtually unobtainable in retail shops during August 1983 to September 1984, and again during 1986. Presumably, most of the available supply of these species is going to the hotel and restaurant trade.

#### 5.2.4 Costs of Marketing Services

For most species, the auction-retail price spread shows a slight upward trend over the period of the data. This is consistent with the increasing cost of providing the market services that are embodied in the retail price of fish such as labour charges for cleaning and filleting whole fish, transport to retail premises, shop rental, electricity and refrigeration, packaging and promotion, etc.

Several species, however, show a declining price spread over part or all of the data period. Examples are gemfish and whiting. This may be due to productivity improvements in processing or retailing being passed onto consumers, which would be unlikely for just these particular species, or to a change in price spread determination behaviour to a more longer run type of price averaging across species.

## 6. CONCLUSIONS

### 6.1 Summary

In this paper, weekly auction-retail prices are calculated and reported for fifteen categories of fish and two categories of crustacea, marketed in the Sydney area between October 1982 and June 1986. The price spreads are calculated by the comparative price method; that is, as the difference between the auction price at the Sydney Fish Markets and an average retail price in the Sydney metropolitan area, for a comparable retail equivalent weight. The fifteen fish categories are gemfish, redfish, flathead, morwong, mullet, trevally, snapper, whiting, bream, kingfish, ling, John dory, Mirror dory, mulloway and garfish. King and school prawns constitute the two crustacea categories.

In the second section of the paper, the fish marketing system in NSW was briefly discussed. This involved an overview of the appropriate marketing regulations, the activities of the NSW FMA, including auctions held at its Sydney Fish Market complex and the relatively simple retail marketing system. Alternative methods for calculating price spreads were outlined in Section 3 and previous research in the meat market was noted. The fourth section contained a description of the procedures and data employed in this study, while the results in the form of Figures were presented in Section 5 (with Tables in the Appendix). These calculated spreads were then examined in terms of their short run movements, their longer run trends, and the effects of known supply and demand conditions.

This exercise has resulted in a number of important observations. First, a set of auction and retail prices for fifteen fish species and two prawn categories, has been collected and collated, and auction-retail price spreads of their differences have been calculated. This is the first time that such information has been available for the NSW fishing industry. Second, data have been compiled on the proportions of the various species sold in the three main processed forms and the grades of fish which go into those processed forms. Third, the reported results confirm the extreme variability in auction prices for fish on a week-to-week basis, and the subsequent variability in retail prices (although to a lesser extent) and in the auction-retail price spread. Fourth, a qualitative examination of the spreads suggested a number of pricing practices which are common in meat retailing. Particularly evident was price levelling, where price spreads vary inversely with changes in the auction price; price averaging, where high spreads on some species subsidise low or even negative spreads on other species; and the strong influence of holiday periods on demand and retail price. Additionally for fish, there is evidence of the impact of supply conditions in the various fisheries on price spread behaviour. Finally, over the longer term it is apparent that most price spreads were gradually expanding in line with rises in the costs of providing the market services that are embodied in the retail price of fish.

## 6.2 Scope for Modelling

Although it has been suggested above that various factors are responsible for the magnitude and variability of the auction-retail price spreads for fish in the Sydney market, more formalised examination techniques are required before it can be confidently concluded that these suppositions are correct. In subsequent work it is proposed, therefore, to specify and estimate an econometric model of price spread behaviour in the Sydney fish market, with a view to testing within a statistical framework the veracity of the suggested or hypothesised factors influencing this behaviour. A number of alternate specifications could be estimated to test for the presence of different types of behavioural decisions. However, as a starting point a model for the price spread of any one species would include as explanatory variables: cost variables, current and previous period's auction price, price spreads of other fish species, seasonal variables for both supply and demand, and the prices of substitute protein sources such as meats and eggs. This research is currently proceeding.
